DSP Report (3)

Experiment (3): Convolution

Estimate the received signal at a receiver if a square signal its amplitude is 3V, duty-cycle equals 30% and frequency is 10000 Hz and is transmitted through a multipath channel with the following specifications:

- Coefficients = [1 0.6 0.15 0.02]
- Delay = [0 1 5 8]

Using two different methods.

Is there a difference between input and output signals? If yes, give a reasonable comment?

- You should clarify on figures which of them is input signal and output signal.
